

Everything you never knew you wanted to know about SAR and B1+RMS, and were too busy to ask.

Dr David Brennan

Department of  
Clinical  
Physics &  
Bioengineering

# Remember when physics was fun?

# The fun never ends...

A calloused, dry hand may have more than 100,000  $\Omega$  because of a thick outer layer of dead cells (usually lower, but still significant). The internal body resistance is about 300  $\Omega$ , being related to the wet, relatively salty tissues beneath the skin.\*

# Oh Wait, the fun is ending...

A 1200W heater.

Fortunately we don't pump in 1200W, but even small wattages can heat tissue up.

# Specific Absorption Rate (SAR)

- The amount of power deposited in a patient per unit weight
  - Power – Watts (W)
  - Weight- Kilogram (Kg)
  - $SAR = W/Kg$
- MRI
  - Normal Mode – Whole body SAR of 2 W/Kg (head SAR 3.2 W/Kg)
  - First Level Mode – Whole Body SAR of 4 W/Kg (head SAR 3.2 W/kg)
- Not Just MRI!
  - Mobile Phones
  - 1.6 W/Kg in the US
  - 2 W/Kg in the EU (Head and trunk)
  - UK after Brexit – Who knows?!

# Is it really that simple?

	Whole body	Partial body			Local Trunk	Extremities
		Head	Not head <sup>a</sup>	Head <sup>b</sup>		
NORMAL MODE	2	3.2	2–10	10	10	20
CONTROLLED MODE	4	3.2	4–10	20	20	40
RESEARCH / EXPERIMENTAL MODE	>4	>3.2	>(4–10)	>20	>20	>40

<sup>a</sup> Partial-body SAR scales dynamically with the ratio  $r$  between the patient mass exposed and the total patient mass:

- normal operating mode:  $SAR = (10-8 \times r) \text{ Wkg}^{-1}$
- controlled operating mode:  $SAR = (10-6 \times r) \text{ Wkg}^{-1}$

<sup>b</sup> In cases where the eye is in the field of a small local coil used for RF transmission, care should be taken to ensure that the temperature rise is limited to 1°C.

Averaging time = 6 min.

Safety Guidelines for Magnetic Resonance Imaging Equipment in Clinical Use, MHRA 2014

# Is it really that simple?

RF penetration and absorption are complex and need to be modelled for different body shapes and sizes.

What's this  $B1_{rms}$  gobbledegook?

**$B1_{rms}$**

The magnetic field generated  
by the RF coil

Root-mean-square (time  
average over all RF pulses)

The particular (positively  
rotating) component of the  
 $B1$  field useful for imaging

What's this B1+rms gobbledygook?

**B1+rms**

A measure of the RF power  
going into the patient  
averaged over 10 seconds

# What's the point?

- B1+rms is independent of patient characteristics
  - Not dependant on patient's weight or height
  - Is dependant in imaging parameters i.e. TR, number & type of RF pules, flip angle etc
- Useful in situations where there is an implant
  - Manufacturers can work out how much RF power an implant can safely tolerate
  - Less conservative than setting SAR which needs to take into account potentially large variations in patient weight

# Goodbye SAR? Long live B1+rms!?

- SAR is and will remain important in determining patient TISSUE heating
  - Patients who have temperature autoregulation dysfunction
  - Patients with fever
  - Infants and children
- B1+rms provides better, less conservative information in patients with IMPLANTS

# Enough with the theory!!

- What is it really good for?
- Likely to increase in use in the future, especially in active implants
- Increased awareness with MRI scanner manufacturers
  - More options to monitor B1+rms and limit it.
- Deep Brain Stimulators, Spinal Cord Stimulators, and some Pacemakers

# Medtronic Advisa and Endura MRI Pacemakers

<b>Scanner type</b>	Horizontal field, cylindrical bore, clinical system for hydrogen proton imaging
<b>Scanner characteristics</b>	<ul style="list-style-type: none"><li>• Static magnetic field of one of the following strengths:<ul style="list-style-type: none"><li>– 1.5 T</li><li>– 3 T</li></ul></li><li>• Maximum spatial gradient of <math>\leq 20</math> T/m (2000 gauss/cm)</li><li>• Gradient systems with maximum gradient slew rate performance per axis of <math>\leq 200</math> T/m/s</li></ul>
<b>Scanner operation</b>	<p><b>1.5T</b> – MRI radio frequency (RF) power – Normal Operating Mode.</p> <ul style="list-style-type: none"><li>• The whole body averaged specific absorption rate (SAR) must be <math>\leq 2.0</math> W/kg.</li><li>• The head SAR must be <math>\leq 3.2</math> W/kg.</li></ul> <p><b>3T</b> – MRI radio frequency (RF) power – First Level Controlled Operating Mode or Normal Operating Mode:</p> <ul style="list-style-type: none"><li>• <math>B_{1+RMS}</math> must be <math>\leq 2.8</math> <math>\mu</math>T when the isocenter (center of the MRI bore) is inferior to the C7 vertebra.</li><li>• Scans can be performed without restriction when the isocenter is at or superior to the C7 vertebra (see Figure 1).</li></ul>

# On the Scanner?

**SAR Information**

Current operating mode: Normal mode (NM)

Operating mode for the next measurement:  Normal mode  First level

**Displayed values belong to the current patient!**

Whole Body	39	[%]
Exposed Body	26	[%]
Head	0	[%]
Head Local	0	[%]
Torso Local	0	[%]
Legs Local	0	[%]
B1+ rms	26	

Calculation time: 15:29:42

B1+ rms [ $\mu$ T] 0.0 1.8 7.1

Prediction | Status | Patient | Protocol | Current

Auto Prescan successful. R1=8 R2=30 TG=152 AX

Minimum TE: 8.8  
Maximum TE: 12.3

**3.00 (2.04)**

SAR mode: low

B1 rms: 2.00  $\mu$ T

Whole body / level: < 0.8 W/kg / no...

PNS / level: 44% / normal

Sound Pressure Le... 9.5

# What does the future hold?

- Implant modes
  - All manufacturers looking to implement
  - Set limit for SAR or B1+rms
- Further in the future....
  - Implant databases
  - How, or would these deal with multiple implants and potential interactions?
  - Who would assume risk?
